Authorized Summary
Project P50 1.3.3 Cell / EMSF

The BESA tests conducted by IFVBESA on the energetic and physical effectiveness of the test object against electromagnetic (interference) fields, including 4G, 5G, and 6G mobile communication technologies, clearly demonstrate its ability to neutralize or harmonize biologically relevant stress factors at acupuncture points. The effects of these stress factors on the meridian system and on energy-informational-biological regulatory circuits were systematically investigated using bioenergy-informational system analysis.

The BESA before-and-after tests show significant changes at the tested acupuncture points of the subjects. The collected measurement data and key figures confirm both the presence of relevant stress factors and their conversion into inherent, biocompatible energies after application of the test object.

Compared to the control group, the experimental group showed a significant improvement in the measured values for all six subjects. These values shifted from the predominantly blue or red measurement range into the green, optimal range (approximately 50 scale points). This indicates a significantly improved regulatory dynamic and a significant optimization of the body's energy situation.

The statistical analysis of the hormone profile using BESA also shows that almost all hormone parameters in the experimental group are within the regulatory range. Overall, the results demonstrate a significant improvement in energy information, which is clearly evident in the BESA post-measurement measurements compared to the pre-measurement measurements..

By demonstrating the energy-informational effectiveness of Cell as a test object against the test subjects (P1-P6) in this project P50 1.3.3, the requirements for receiving a BESA seal of approval from the International Professional Association for BESA were met.
